Algorithms Worksheet 4

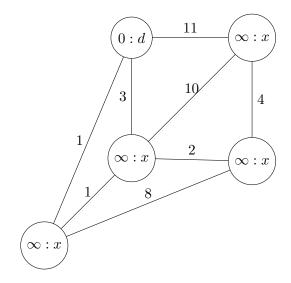

This week there are two question each worth four marks, there are two marks for attendance.

1. Us Dijkstra's algorithm to find the shortest path from d to c in

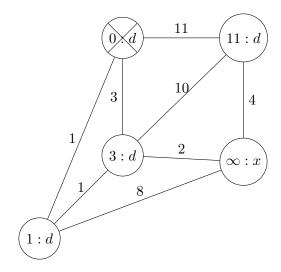

Solution:

Set the distances as ∞ except the first node, the x shows there is no preceding node.

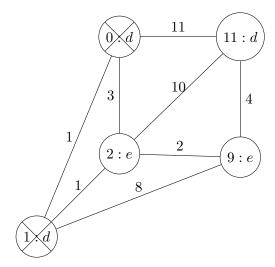

Update the nodes adjacent to the starting node:

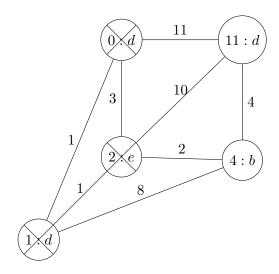

COMS10001 - PandA2 algorithms worksheet 4 - Conor

Take the lowest distance node and update that:

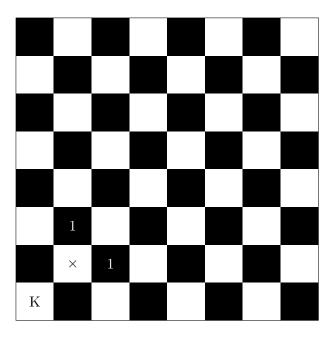

And again

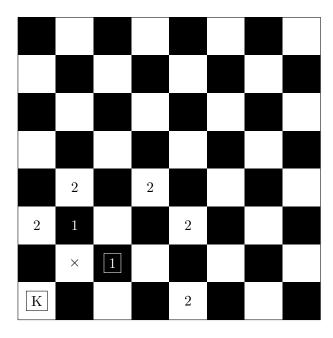

Since the target node is the lowest available node the algorithm stops and, following back the route is debc.

2. In chess a knight moves three squares in one cardinal direction followed by one square in a perpendicular direction. In the chess board below the knight is in the bottom left-hand position, the two squares that it can reach in one move are marked '1', what is the least number of moves that will take it to the square marked ×?

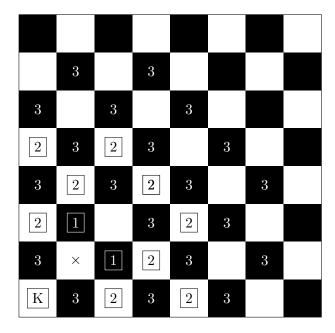

Solution:

This is just a version of Dijkstra's algorithm, do each node in turn and then cross if off, let's use a box to mark the crossed off nodes.

COMS10001 - PandA2 algorithms worksheet 4 - Conor

Now all the '3' squares are going to be black, so the knight can't reach the \times this go, so let's deal with all the '2' squares straight away.

The next move will reach the \times so the answer is four.
